webSME
a tool for interactive stellar abundance work

(ChETEC-INFRA 3rd General Assembly, 6 June, 2023)

UPPSALA UNIVERSITET

Outline

1) Motivation and aim

2) Relevant stellar parameters

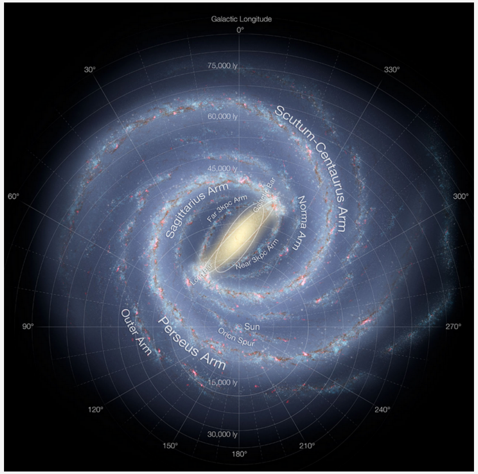
3) Live Pipeline Presentation

1) Motivation and aim

- In the context of **Galactic archaeology** we want to understand the formation of stellar populations in the Milky Way, e.g.: How did the prominent bar in the Milky Way form?

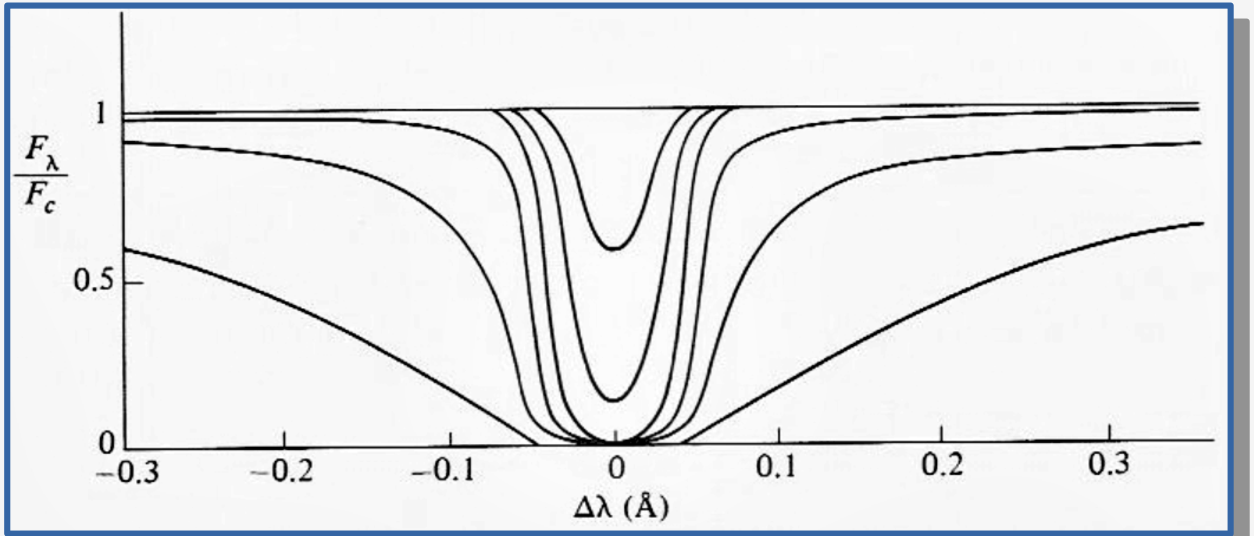
- The stars are our fossils that provide insight into the formation history and evolution of the Milky Way.

→ We need to measure accurately the **chemical composition** (and dynamics) of the stars.



1) Motivation and aim

Principle: Spectral line shapes contain information about the number of absorbing atoms/ions along line of sight → column density N_a (of element in observed state)



Example: Voigt profiles of Ca II K lines produced by N_a~10^{11} cm^{-2} in the shallowest case up to ~10^{16} cm^{-2} (change by factor 10 per line).

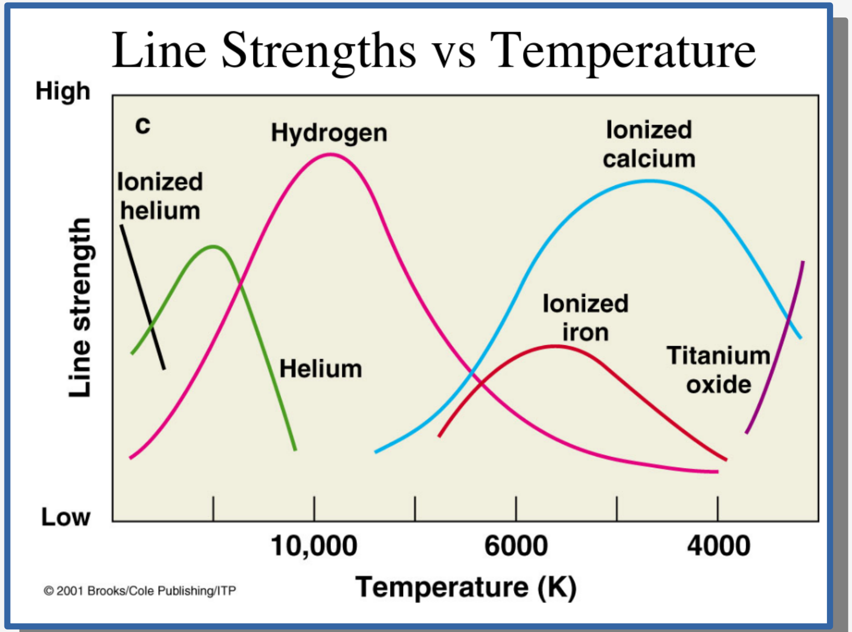
2) Stellar parameters

Stellar photospheres can be characterized by a handful of parameters:

→ Effective temperature (Teff)

temperature of a black body with the same integrated flux as star

$$\int F \, d\lambda = \sigma_B T_{eff}$$



2) Stellar parameters

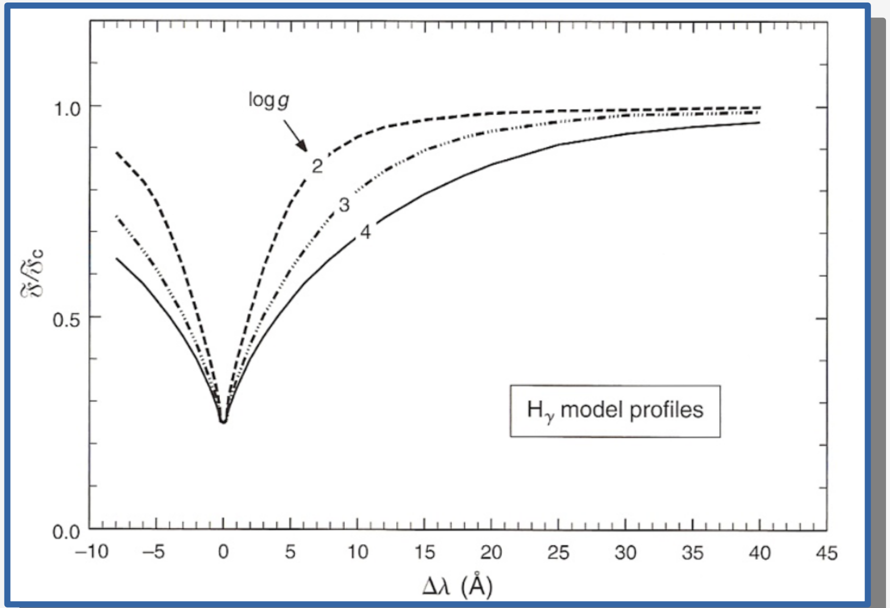
Stellar photospheres can be characterized by a handful of parameters:

→ **Surface gravity log g**

logarithm of the gravitational acceleration at the surface of the star

$$g \propto M/R^2$$

In the outer layers of the star, where the spectrum is created and mass is essentially independent of the radius, log g determines gas density!



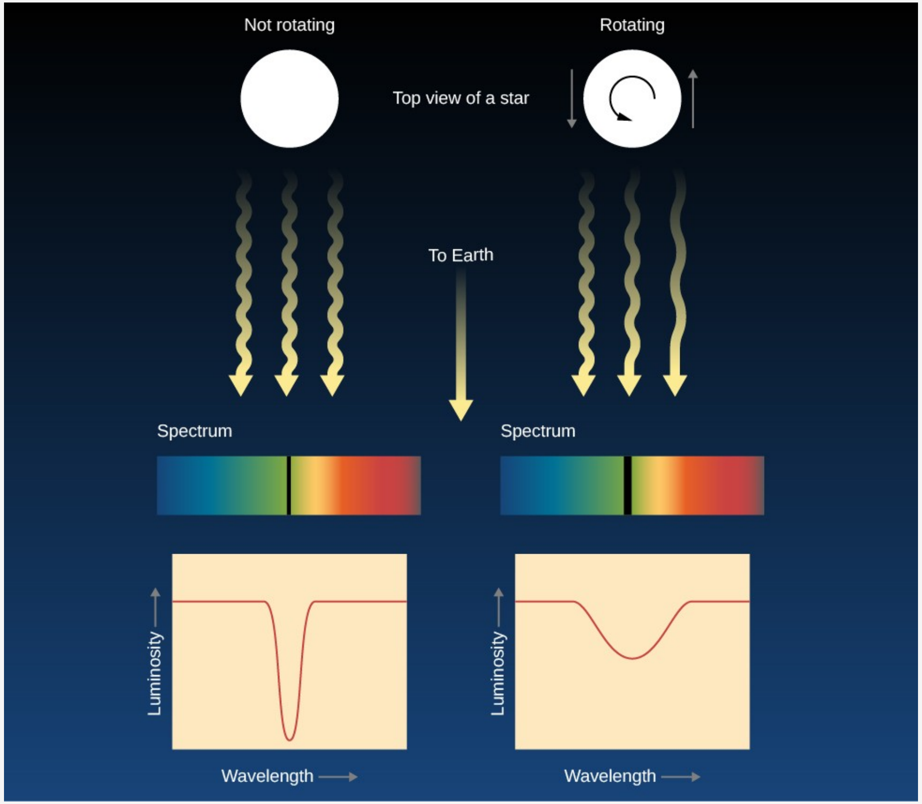
Gray 2005, Stellar Photospheres, CUP

2) Stellar parameters

Stellar photospheres can be characterized by a handful of parameters:

→ Projected rotational velocity $v \sin(i)$

stellar rotation as seen from Earth, with i being the inclination of the rotation axis relative to line of sight



https://openstax.org/books/astronomy/pages/1-introduction

2) Stellar parameters

- Stellar photospheres can be characterized by a handful of parameters:

  → microturbulence v_{mic} and macroturbulence v_{mac}

  high-order pulsations, turbulence, convection and stellar activity cannot be spatially resolved → v_{mic} and v_{mac} are used to describe effects on line

motions on scales < mean free path length
→ increased line opacity

motions on scales > mean free path length
→ change line shape, not strength

3) webSME

Evolution of "Spectroscopy Made Easy":

- SME: Original version published by Valenti & Piskunov (1996)
  `C++` and `FORTRAN` library
  complemented by IDL framework
- Library has undergone significant development (Piskunov & Valenti 2017)
- pySME: Wehrhahn et al. (2022) translated IDL part of code to `python`
- webSME: based on pySME, with some updates...

3) webSME

- **New features:**

  i) a web interface that allows users to upload and visualize observed spectra

  ii) implementation of (parallel tempered) MCMC routines to infer uncertainties of the derived parameters

- **Update** of intrisic features to produce results based on the latest developments in the field:

  i) we make use of the Gaia-ESO line list of Heiter et al. (2021)

  ii) inclusion of the most recent solar reference abundances of Asplund, Amarsi and Grevesse (2021) to allow for accurate metallicity derivations.
